Aquaculture Machine Learning Analysis

Fish Weight Prediction Model

Linear Regression with PCA Analysis

Generated: February 05, 2026 at 08:59 PM

Dataset: 39 samples | 11 features

Target Variable: AVG WEIGHT 1 (Fish Final Weight)

Executive Summary

EXECUTIVE SUMMARY
==========

Dataset Overview
- Total Samples: 39
- Training Set: 31 samples (79.5%)
- Testing Set: 8 samples (20.5%)
- Features: 11
- Target: AVG WEIGHT 1 (Fish Final Weight)

Target Variable Statistics
- Range: 0.300 - 0.600 kg
- Mean: 0.431 kg
- Standard Deviation: 0.074 kg
- Median: 0.450 kg

Model 1: Linear Regression (All Features)
- Training R^2: 0.6770 (67.70% variance explained)
- Testing R^2: 0.5229 (52.29% variance explained)
- Cross-Validation R^2: -2.0308 ± 2.4222
- RMSE: 0.0584 kg
- MAE: 0.0464 kg

Model 2: Linear Regression with PCA
- Components: 7 (from 11 features)
- Variance Retained: 95.44%
- Testing R^2: 0.3354 (33.54% variance explained)
- RMSE: 0.0689 kg
- MAE: 0.0608 kg

Best Model: Linear Regression
- Achieves 52.29% accuracy on test set
- Average prediction error: ±0.0464 kg
- Higher accuracy with all features

Top 3 Most Important Features
1. HARVEST NO. 1: -0.1420
2. PRODUCTION 1: 0.0912
3. DISTANCE/m: 0.0421

Key Insight
The most influential factor is HARVEST NO. 1 with a
negative correlation,
suggesting that lower
values lead to decreased fish weight.

Recommendations & Conclusions

RECOMMENDATIONS & CONCLUSIONS
==

Best Model Selection
  ✓ Recommended Model: Linear Regression
  ✓ Test R^2 Score: 0.5229 (52.29% accuracy)
  ✓ Average Error: ±0.0464 kg (46.4 grams)
  ✓ Explains 52.29% of fish weight variation

Model Interpretation
  The model indicates that fish final weight is primarily influenced by:

  1. HARVEST NO. 1 (Coefficient: -0.1420)
     ↓ Higher values → Lighter fish

  2. PRODUCTION 1 (Coefficient: 0.0912)
     ↑ Higher values → Heavier fish

  3. DISTANCE/m (Coefficient: 0.0421)
     ↑ Higher values → Heavier fish

Practical Applications
  • Predict final fish weight based on farming conditions
  • Optimize stocking density and feeding strategies
  • Estimate harvest timing for target weights
  • Identify which factors most impact fish growth

Model Limitations
  • Based on 39 historical samples
  • Predictions most reliable within training data range (0.300 - 0.600 kg)
  • Linear relationship assumed between features and weight
  • External factors (disease, weather) not included

PCA Insights
  • Dimensionality reduced from 11 to 7 features
  • Retained 95.44% of information
  • Simpler model with acceptable accuracy trade-off
  • Consider PCA model for deployment if simplicity is priority

Next Steps
  ✓ Deploy Linear Regression in production
  ✓ Monitor predictions on new data
  ✓ Retrain periodically with updated samples
  ✓ Consider ensemble methods for improved accuracy
  ✓ Collect more data for better generalization

Data Quality Notes
  • 4 samples excluded due to missing values
  • DENSITY column had 0 #REF! errors (cleaned)
  • Consider data collection improvements for future cycles
